(54) Abstract Title

**Method and system for displaying scaled, precise maps on personal navigational aids**

(57) The invention provides for a system and method in which the global position of a mobile terminal is estimated from GPS (global positioning system) signals transmitted from a number of GPS satellites and received by the mobile terminal. The degree of precision of the estimated global position is determined and the size, or scale of an area to be displayed is determined according to the degree of precision, and a map of the area of the determined size is generated according to the global position of the mobile terminal, and displayed on the mobile terminal.

The present invention relates generally to global positioning systems, and more specifically to a method and system for displaying maps for personal navigational aid.

The global positioning system, or GPS, has recently been used extensively for application to wireless mobile terminals to serve as a personal navigational aid. According to the current method, the mobile terminal receives signals from GPS satellites and determines its global position by processing the received signals and transmits a request via a mobile communications network to a map server for a map. The request contains information as to the mobile's global position and the scale of the map (i.e., the size of the geographical area to be displayed). In response, the map server produces a map of the requested scale and communicates this map to the mobile terminal for display. However, due to the presence of hindrances in the paths of signals from line-of-sight GPS satellites, the received signals may be disrupted or may lose critical data, particularly when the user is moving around built-up areas. As a result, the user may not be satisfied with the displayed map, and transmits a request again to the map server to alter the scale of the map. The process will be repeated until the displayed map meets the user's satisfaction. However, this is tedious and time-consuming.

1       Therefore, there exists a need for eliminating the manual process of  
2 determining the scale of a map displayed on a wireless mobile terminal.

3       According to a first aspect of the present invention, there is provided a  
4 method of displaying a map on a mobile terminal, comprising the steps of  
5 estimating a global position of the mobile terminal from signals transmitted  
6 from a plurality of GPS (global positioning system) satellites and received by  
7 the mobile terminal, determining a degree of precision of the estimated global  
8 position of the mobile terminal, determining a size of an area to be displayed  
9 according to the degree of precision, generating a map of the area of the  
10 determined size according to the global position of the mobile terminal, and  
11 displaying the map on the mobile terminal.

12       According to a second aspect, the present invention provides a mobile  
13 communication system comprising a communications network, a server  
14 connected to the network for estimating a global position from received GPS  
15 signals, and a mobile terminal for receiving GPS signals from GPS satellites  
16 and transmitting the received GPS signals to the server station via the  
17 communications network to cause the server station to determine the global  
18 position of the mobile terminal. The server determines a degree of precision  
19 of the estimated global position of the mobile terminal and determines the  
20 size of an area to be displayed on the mobile terminal according to the degree  
21 of precision, generates a map of the area of the determined size according to  
22 the global position of the mobile terminal and communicates the generated  
23 map to the mobile terminal.

24       According to a third aspect, the present invention provides a mobile  
25 communication system comprising a communications network, a mobile  
26 terminal for receiving GPS signals from GPS satellites, and a server. The

1 mobile terminal estimates its global position from the received GPS signals,  
2 determines a degree of precision of the estimated global position of the  
3 mobile terminal and determines the size of an area to be displayed on the  
4 mobile terminal according to the degree of precision. From the mobile  
5 terminal a server receives information as to the global position of the mobile  
6 terminal and the size of the map via the network, generates a map of the area  
7 of the size according to the received information and communicates the map  
8 to the mobile terminal via the network.

9  
10 It is therefore an advantage of the present invention that a method and  
11 system for automatically displaying a map of appropriate scale on a mobile  
12 terminal can be provided.

13 The invention also advantageously allows for the determination of a  
14 degree of precision of estimated mobile position and determining the scale of  
15 a map according to the determined degree of precision.

16  
17 The present invention will be described in detail further with reference  
18 to the following drawings, in which:

19 Fig. 1 is a block diagram of a communication system according to a  
20 first embodiment of the present invention;

6        and

7        Fig. 8 is a flowchart of the operation of a server of Fig. 1 when the  
8        mobile terminal is in a moving vehicle.

9

10       In Fig. 1, there is shown a communication system according to a first  
11       embodiment of the present invention. The communication system is  
12       comprised of a communications network 3 to which a plurality of wireless  
13       base stations 2 and a GPS (global positioning system) station 4 are connected.

14       A user mobile terminal 1 operates with a radio transceiver 11 to set up  
15       a wireless link to a nearby base station. A communication controller 12  
16       performs communication control of the terminal 1 with the base station  
17       according to the known protocol. A central processing unit (CPU) receives  
18       signals from the controller 12 and saves the signals in a memory 14 to display  
19       a map on a display panel 15. User instructions are entered through a keypad  
20       16 to the CPU 13. A GPS antenna 17 is provided to receive signals from GPS  
21       satellites and a GPS processor 18 processes the received GPS signals. The  
22       processed signals are supplied to the CPU. In a first embodiment of the  
23       present invention, the CPU produces a precision GPS signal from the signals  
24       directly received from the satellites and supplemental GPS data obtained  
25       from the GPS station 4.

1           GPS station 4 is comprised of a GPS antenna 21, a GPS receiver 22, a  
2   position finder server 23 and a map server 24. Both servers 23 and 24 are  
3   connected by a bus system to a server controller 25, which is in turn  
4   connected to the communications network 3 to exchange signals with the  
5   mobile terminal 1 via one of the base stations 2. The GPS receiver 22  
6   processes signals detected by the GPS antenna 21 and produces the  
7   supplemental GPS data by using the signals supplied from the GPS antenna  
8   21 and the signals received from the mobile terminal 1.

9           The operation of the server controller 25 according to the first  
10   embodiment will be explained below with reference to the flowchart of Fig. 2.

11           Initially, the mobile terminal sends a request to the server controller 25  
12   for supplemental data. In response to the request from the mobile terminal 1  
13   (step 201), the server controller 25 establishes a link between the mobile  
14   terminal and the position finder server 23 and retrieves supplemental data  
15   from the server 23, indicating the identification numbers of line-of-sight GPS  
16   satellites, and transmits it to the mobile terminal (step 202). On the other  
17   hand, the mobile terminal 1 is receiving GPS signals from the line-of-sight  
18   GPS satellites. Using the supplemental data from the server controller and  
19   the received GPS signals, the mobile terminal 1 calculates a pseudorange and  
20   transmits it as a precision GPS signal to the GPS station 4 via the  
21   communications network 3.

22           When the server controller 25 receives the precision GPS signal from  
23   the mobile terminal 1 (step 203), it instructs the position finder server 23 to  
24   determine the global position of the mobile terminal by using the precision  
25   GPS signal (step 204). Further, the server controller uses the precision GPS

1 signal to determine the constellatory positions of line-of-sight GPS satellites  
2 from which the mobile terminal has actually received the GPS signals and  
3 performs map scaling subroutine 200.

4 In the map scaling subroutine, the server controller uses the position  
5 data of the satellites and analyzes it to determine the constellatory positions  
6 of the satellites. According to their constellatory positions, the server  
7 controller divides the satellites into a group of four sectors, or quadrants in  
8 the constellation and determines the number of quadrants in which the line-  
9 of-sight GPS satellites are currently located as a measure of the degree of  
10 precision of estimated position of the mobile terminal.

11 Fig. 3A shows one example of constellatory positions of line-of-sight  
12 GPS satellite where the solid dots represent GPS satellites. In the illustrated  
13 example, the satellites are distributed relatively equally among the four  
14 quadrants of the constellation, and hence the number of quadrants where the  
15 line-of-sight satellites exist is four. Note that the center of the circles  
16 corresponds to the position where the mobile user terminal is located. In Fig.  
17 3B, the line-of-sight GPS satellites are shown unequally distributed possibly  
18 due to hindrance by terrain or building structures so that only two satellites  
19 are in line of sight in each of the first (north-east) and fourth (south-east)  
20 quadrants to the mobile terminal and no satellites are in line of sight in the  
21 second and third quadrants. In the case of Fig. 3B, the number of quadrants  
22 containing line-of-sight GPS satellites is two.

23 Returning to Fig. 2, the map scaling subroutine 200 begins with  
24 decision step 205 to make a decision as to whether the line-of-sight GPS  
25 satellites exist in all the four quadrants. If this is the case, flow branches out

1 to step 206 to select a 50-meter x 50-meter square area and proceeds to the  
2 end of the subroutine. If the decision at step 205 is negative, flow proceeds to  
3 step 207 to determine if the line-of-sight satellites only exist in three  
4 quadrants. If so, a 100-meter x 100-meter square area is selected (step 208). If  
5 the decision at step 207 is negative, flow proceeds to step 209 to determine if  
6 the line-of-sight satellites only exist in two quadrants. If so, a 200-meter x  
7 200-meter square area is selected (step 210). If the decision at step 209 is  
8 negative, a 500-meter x 500-meter square area is selected (step 211).

9 When the execution of subroutine 200 ends, flow proceeds to step 212  
10 in which the server controller informs the map server 24 of the current  
11 position of the mobile terminal (as determined at step 204) and instructs it to  
12 send map data of the selected area to the user terminal. On receiving the map  
13 data, the user terminal displays a map on its display panel.

14 In a modified embodiment of the present invention, instead of the  
15 constellatory positions of line-of-sight GPS satellites, the signal-to-noise ratio  
16 (SNR) of the GPS signal and the number of GPS satellites transmitting signals  
17 of relatively high SNR are used to make decisions as to the scale of the map.

18 The modified map scaling subroutine 300 is shown in Fig. 4.

19 In Fig. 4, the subroutine 300 begins with step 401 which determines  
20 whether there are three or more satellites which are transmitting GPS signals  
21 with SNR higher than 35 dB. If the decision is affirmative, flow proceeds to  
22 step 402 to select a 50-meter x 50-meter square area. If the decision is  
23 negative at step 401, flow proceeds to step 403 to determine whether there are  
24 only two satellites whose SNR value is greater than 35 dB. If so, flow  
25 proceeds from step 403 to step 404 to determine whether there is at least one

1 satellite whose SNR value is in the range between 25 dB and 35 dB. If this is  
2 the case, flow proceeds from step 404 to step 405 to select a 100-meter x 100-  
3 meter square area. If the decision at step 403 or step 404 is negative, flow  
4 proceeds to step 406 to determine whether there is at least one satellite whose  
5 SNR value is greater than 35 dB. If so, flow proceeds to step 407 to make a  
6 further decision as to whether there is at least one satellite whose SNR ratio is  
7 in the range between 25 dB and 35 dB. If this is the case, flow proceeds from  
8 step 407 to step 408 to select a 200-meter x 200-meter square area. If the  
9 decision at step 406 or step 407 is negative, flow proceeds to step 409 to select  
10 a 500-meter x 500-meter square area.

11 Fig. 5 shows a further modification of the map scaling subroutine,  
12 which begins with step 501 which determines whether the line-of-sight GPS  
13 satellites exist in all four quadrants of the constellation. If so, flow proceeds  
14 to step 502 to set a variable D to 1, and if not, flow branches out to step 503 to  
15 determine if the line-of-sight satellites exist only in three quadrants. If so,  
16 flow proceeds to step 504 to set the variable D to 2, and if not, flow proceeds  
17 to step 505 to determine if there are only two quadrants in which the line-of-  
18 sight satellites exist. If so, flow proceeds to step 506 to set the variable D to 3.  
19 Otherwise, flow proceeds to step 507 to set the variable D to 4.

20 Following the execution of each of steps 502, 504, 506, 507, flow  
21 proceeds to step 508 to determine if there are at least three satellites whose  
22 SNR value is higher than 35 dB. If so, a variable S is set to 1 at step 509.  
23 Otherwise, flow proceeds from step 508 to step 510 determine if there are two  
24 satellites whose SNR value is higher than 35 dB. If so, a further decision is  
25 made at step 511 as to whether there is at least one satellite whose SNR value

1 is in the range between 25 dB and 35 dB. If so, flow proceeds to step 512 to  
2 set the variable S to 2. If the decision at step 510 or 511 is negative, a further  
3 decision is made at step 513 as to whether there is at least one satellite whose  
4 SNR value is higher than 35 dB, and if so, flow proceeds to step 514 to  
5 determine if there is at least one satellite whose SNR value is in the range  
6 between 25 dB and 35 dB. If the decision is affirmative at step 514, the  
7 variable S is set to 3 at step 515. If the decision at step 513 or 514 is negative,  
8 the variable S is set equal to 4 at step 516. Following the execution of each of  
9 steps 509, 512, 515 and 516, flow proceeds to decision step 517 to compare the  
10 variables D and S with one another.

11 If  $D = S = 1$ , 50-meter x 50-meter square area is selected (step 518). If  $D$   
12  $= S = 2$ , 100-meter x 100-meter square area is selected (step 519). If  $D = S = 3$ ,  
13 200-meter x 200-meter square area is selected (step 520). If  $D = S = 4$ , 400-  
14 meter x 400-meter square area is selected (step 521). If D is not equal to S, an  
15 intermediate area is selected depending on their relative values (step 522). If  
16  $D = 1$  and  $S = 2$ , for example, an area of 75-meter by 75-meter square is  
17 selected.

18 In the embodiments described above, the map scaling subroutine is  
19 performed by the GPS station 4. The map scaling subroutine can be  
20 performed by the user's mobile terminal 1 in a communications system  
21 shown in Fig. 6.

22 In Fig. 6, the mobile terminal 1 establishes a wireless link with one of  
23 the base stations 2 and establishes a connection to the map server 5 via the  
24 communications network 3. The operation of the mobile terminal 1 proceeds  
25 according to the flowchart of Fig. 7, in which the routine begins with step 701

1 to receive GPS signals and process the received signals to produce a precision  
2 GPS signal and estimate the global position of the mobile terminal using the  
3 precision GPS signal. At step 702, the mobile terminal performs the map  
4 scaling subroutine of either Fig. 2, 4 or 5 to determine the degree of precision  
5 of the estimated global position of the mobile terminal and select an area size.  
6 At step 703, the mobile terminal sends a request indicating the global position  
7 of the mobile terminal and the selected area size to the map server 5. Map  
8 server 5 generates a map of a geographic area according to the informed  
9 global position and scales the map according to the selected area size and  
10 transmits visual information containing the generated map to the mobile  
11 terminal 1. Mobile terminal 1 thus obtains a map of the area at the selected  
12 scale where the mobile terminal is in. At step 704, the obtained map is then  
13 displayed on the mobile terminal.

14 Fig. 8 illustrates a flowchart of the operation of the server controller of  
15 Fig. 1 according to another embodiment of the present invention. This  
16 embodiment is particularly useful for applications where the user is driving  
17 an automobile.

18 Mobile terminal 1 is located in a moving vehicle. The terminal initially  
19 receives signals from the GPS satellites and processes the signals to produce  
20 precision GPS signal without supplemental data from the network and  
21 transmits a request to the network containing the precision GPS signal for a  
22 map of the area where the vehicle is moving around.

23 In response to the request from the mobile terminal (step 801), the GPS  
24 station 5 processes the precision GPS signal contained in the request and  
25 determines the initial position of the moving vehicle (step 802). Then, the

1 routine proceeds to step 803 to wait a predetermined amount of time. At step  
2 804, the GPS station obtains the most recent precision GPS signal from the  
3 mobile terminal and determines its subsequent vehicle position. At step 805,  
4 the initial and subsequent positions of the mobile terminal are used to  
5 calculate its speed of the vehicle. The calculated speed is then compared, at  
6 step 806, with a preset value. If the calculated speed is lower than the preset  
7 value, map data of normal scale is generated according to the normal mode of  
8 operation and the map data is transmitted to the mobile terminal (step 807).  
9 If the calculated speed is higher than the preset value, a map of wide area is  
10 generated according to the detected positions of the vehicle and the  
11 information of the map is transmitted to the mobile terminal for display (step  
12 808).

13 While the embodiments of Figs. 2 and 8 are based on the known  
14 network driven system and the standalone system, respectively, the present  
15 invention could equally be as well implemented using the known network  
16 assist system in which the global position of the mobile terminal is estimated  
17 by the mobile terminal after receiving GPS signals from a GPS server.

CLAIMS

1           1.     A method of displaying a map on a mobile terminal,  
2     comprising the steps of:

3           a)     estimating a global position of said mobile terminal from  
4     signals transmitted from a plurality of GPS (global positioning system)  
5     satellites and received by said mobile terminal;

6           b)     determining a degree of precision of the estimated global  
7     position of said mobile terminal;

8           c)     determining a size of an area to be displayed according to said  
9     degree of precision;

10          d)     generating a map of said area of said determined size according  
11     to said global position of said mobile terminal; and

12          e)     displaying said map on said mobile terminal.

1           2.     The method of claim 1, wherein step (a) comprises the steps of:  
2     receiving, at said mobile terminal, the signals transmitted from said  
3     GPS satellites;

4     receiving, at a GPS system, the signals transmitted from said GPS  
5     satellites, producing therefrom supplemental GPS data and transmitting the  
6     supplemental GPS data to the mobile terminal;

7     producing, at said mobile terminal, a precision GPS signal by using the  
8     signals of the GPS satellites received at the mobile terminal and said  
9     supplemental GPS data from said GPS system; and

10          determining, at said GPS system, said global position of the mobile  
11     terminal from said precision GPS signal.

1           3.     The method of Claim 1, wherein step (a) comprises the steps of:  
2           receiving, at said mobile terminal, signals from said plurality of GPS  
3     satellites and producing therefrom a precision GPS signal; and  
4           determining, at said mobile terminal, a global position of the mobile  
5     terminal.

1           4.     The method of Claim 1, 2 or 3, wherein step (b) comprises the steps of:  
2           determining constellatory positions of line-of-sight GPS satellites from  
3     said precision GPS signal and determining from said constellatory positions a  
4     number of equally divided areas of constellation in which said line-of-sight  
5     GPS satellites exist; and  
6           determining said degree of precision of the estimated global position  
7     from the determined number of said divided areas.

1           5.     The method of Claim 1, 2 or 3, wherein step (b) comprises the steps of:  
2           determining a number of GPS satellites whose transmissions are  
3     higher than a predetermined signal-to-noise ratio; and  
4           determining said degree of precision of the estimated global position  
5     from the determined number of GPS satellites.

1           6.     The method of Claim 1, 2 or 3, wherein step (b) comprises the steps of:  
2           determining constellatory positions of line-of-sight GPS satellites from  
3     said precision GPS signal and determining from said constellatory positions a  
4     number of equally divided areas of constellation in which said line-of-sight  
5     GPS satellites exist;  
6           determining a number of GPS satellites whose transmissions are

7 higher than a predetermined signal-to-noise ratio; and  
8 determining said degree of precision of the GPS signal from a  
9 combination of the determined number of said divided areas and the  
10 determined number of said GPS satellites.

1 7. The method of any one or more of Claims 1 to 6, further comprising the steps of:  
2 successively receiving, at said GPS station, a plurality of said precision  
3 GPS signal from said mobile terminal during a predetermined time interval  
4 and determining therefrom initial and subsequent global positions of said  
5 mobile terminal;  
6 determining a moving speed of said mobile terminal from said initial  
7 and subsequent global positions of the mobile terminal; and  
8 generating, according to said global positions, a map of an area of  
9 normal size when the determined moving speed is lower than a  
10 predetermined value and a map of an area larger than the normal size when  
11 the determined moving speed is higher than said predetermined value.

1 8. A mobile communication system comprising:  
2 a communications network;  
3 a server connected to the network for determining a global position  
4 from received GPS (global positioning system) signals; and  
5 a mobile terminal for receiving GPS signals from GPS satellites and  
6 transmitting the received GPS signals to said server station via said  
7 communications network to thereby cause said server station to estimate the  
8 global position of the mobile terminal,  
9 said server determining a degree of precision of the estimated global

10 position of said mobile terminal and determining the size of an area to be  
11 displayed on said mobile terminal according to said degree of precision,  
12 generating a map of said area of said determined size according to said global  
13 position of said mobile terminal and communicating the generated map to  
14 said mobile terminal.

1           9.     The mobile communication system of claim 8, wherein said  
2 server determines constellatory positions of line-of-sight GPS satellites from  
3 said precision GPS signal and determines from said constellatory positions a  
4 number of equally divided areas of constellation in which said line-of-sight  
5 GPS satellites exist, and determines said degree of precision of the estimated  
6 global position from the determined number of said divided areas.

1           10.    The mobile communication system of claim 8, wherein said  
2 server determines a number of GPS-satellites whose transmissions are higher  
3 than a predetermined signal-to-noise ratio, and determines said degree of  
4 precision of the estimated global position from the determined number of  
5 GPS satellites.

1           11.    The mobile communication system of claim 8, wherein said  
2 server determines constellatory positions of line-of-sight GPS satellites from  
3 said precision GPS signal, determines from said constellatory positions a  
4 number of equally divided areas of constellation in which said line-of-sight  
5 GPS satellites exist, determines a number of GPS satellites whose  
6 transmissions are higher than a predetermined signal-to-noise ratio, and  
7 determines said degree of precision of the estimated global position from a

8 combination of the determined number of said divided areas and the  
9 determined number of said GPS satellites.

1 12. The mobile communication system of Claim 8, 9, 10 or 11, wherein said  
2 server successively receives a plurality of said precision GPS signal from said  
3 mobile terminal during a predetermined time interval and determines  
4 therefrom initial and subsequent global positions of said mobile terminal,  
5 determines a moving speed of said mobile terminal from said initial and  
6 subsequent global positions of the mobile terminal, and generates, according  
7 to said global positions, a map of an area of normal size when the determined  
8 moving speed is lower than a predetermined value and a map of an area  
9 larger than the normal size when the determined moving speed is higher  
10 than said predetermined value.

1 13. A mobile communication system comprising:  
2 a communications network;  
3 a mobile terminal for receiving GPS (global positioning system) signals  
4 from GPS satellites, estimating a global position of the mobile terminal from  
5 the received GPS signals, determining a degree of precision of the estimated  
6 global position and determining the size of an area to be displayed on said  
7 mobile terminal according to said degree of precision; and  
8 a server for receiving from said mobile terminal information of said  
9 global position and said size via said network, generating a map of said area  
10 of said determined size according to the received information and  
11 communicating the map to said mobile terminal via said network.

1           14.    The mobile communication system of claim 13, wherein said  
2   mobile terminal determines constellatory positions of line-of-sight GPS  
3   satellites from said precision GPS signal and determines from said  
4   constellatory positions a number of equally divided areas of constellation in  
5   which said line-of-sight GPS satellites exist, and determines said degree of  
6   precision of the estimated global position from the determined number of  
7   said divided areas.

1           15.    The mobile communication system of claim 13, wherein said  
2   mobile terminal determines a number of GPS satellites whose transmissions  
3   are higher than a predetermined signal-to-noise ratio, and determines said  
4   degree of precision of the estimated global position from the determined  
5   number of GPS satellites.

1           16.    The mobile communication system of claim 13, wherein said  
2   mobile terminal determines constellatory positions of line-of-sight GPS  
3   satellites from said precision GPS signal, determines from said constellatory  
4   positions a number of equally divided areas of constellation in which said  
5   line-of-sight GPS satellites exist, determines a number of GPS satellites whose  
6   transmissions are higher than a predetermined signal-to-noise ratio, and  
7   determines said degree of precision of the estimated global position from a  
8   combination of the determined number of said divided areas and the  
9   determined number of said GPS satellites.

1           17.    A method of displaying a map on a mobile terminal substantially as  
2   hereinbefore described with reference to, and as illustrated in, the accompanying  
3   drawings.

- 1        18.    A mobile communication system substantially as hereinbefore
- 2        described with reference to and as illustrated by the accompanying drawings.
